Probabilistic classifiers

Probabilistic classifiers are classifiers that predict, given an observation of an input, a **probability distribution over a set of classes** (instead of simply the class like standard classifiers).

Probabilistic classifiers

Probabilistic classifiers are classifiers that predict, given an observation of an input, a **probability distribution over a set of classes** (instead of simply the class like standard classifiers).

Given a record $\mathbf{x} = (x_1, x_2, \dots, x_n) \in \mathbb{R}^n$ and a set of labels $y_i \in \mathcal{Y}$, provide an estimation of $\mathbb{P}(y_i|\mathbf{x})$ $y_i \in \mathcal{Y}$ (and assign most likely label to \mathbf{x}).

Question

What is in your opinion one of the strength of working with a probabilistic model rather than a classification function ?

Possible native models are:

- Logistic regression
- Subtypes of neural networks
- Bayes classifiers

Question

What is in your opinion one of the strength of working with a probabilistic model rather than a classification function ?

Possible native models are:

- Logistic regression
- Subtypes of neural networks
- Bayes classifiers

Non-probabilistic models can also be turned into a probabilistic classifier (SVM, trees ...).

The naïve Bayes classifier algorithm

The naïve Bayes classifier algorithm is a probabilistic classifier based on applying Bayes' theorem with independence assumptions between the features.

Hyperparameters

Advantages
and limits

Further
algorithms

The naïve Bayes classifier algorithm

The naïve Bayes classifier algorithm is a probabilistic classifier based on applying Bayes' theorem with independence assumptions between the features.

Each features **contribute to the class probability independently**: for example, the size and the weight of the dog contribute independently to its breed.

Further
algorithms

We want to estimate for each label $y_i \in \mathcal{Y}$ $\mathbb{P}(y_i|\mathbf{x})$ (*what is the probability of being label y_i given the data records ?*) .

Mathematical framework

prediction

Hyperparameters

Advantages
and limits

Further
algorithms

We want to estimate for each label $y_i \in \mathcal{Y}$ $\mathbb{P}(y_i|\mathbf{x})$ (*what is the probability of being label y_i given the data records ?*) .

However, if n is large, the computation is infeasible.

Using the definition of conditional probabilities:

$$\mathbb{P}(y_i|\mathbf{x}) = \frac{\mathbb{P}(y_i, \mathbf{x})}{\mathbb{P}(\mathbf{x})}$$

$P(\mathbf{x})$ is a constant because \mathbf{x} is given so we only need to find the value of $\mathbb{P}(y_i, \mathbf{x})$.

Mathematical framework

Hyperparameters

Advantages
and limits

Further
algorithms

Using the definition of conditional probabilities iteratively,

$$\begin{aligned}\mathbb{P}(y_i, \mathbf{x}) &= \mathbb{P}(x_1, x_2, \dots, x_n, y_i) \\ &= \mathbb{P}(x_1 | x_2, x_3, \dots, y_i) \times \mathbb{P}(x_2, x_4, \dots, y_i) \\ &= \mathbb{P}(x_1 | x_2, x_3, \dots, y_i) \times \mathbb{P}(x_2 | x_3, x_4, \dots, y_i) \times \mathbb{P}(x_3, x_4, \dots, y_i) \\ &= \dots \\ &= \mathbb{P}(x_1 | x_2, x_3, \dots, y_i) \times \mathbb{P}(x_2 | x_3, x_4, \dots, y_i) \times \mathbb{P}(x_n | y_i) \times \mathbb{P}(y_i)\end{aligned}$$

Hyperparameters

Advantages
and limits

Further
algorithms

We now make the hypothesis that each feature x_i is independant (and only depends on the label y_i):

$$\mathbb{P}(x_1|x_2, x_3, \dots, y_i) = \mathbb{P}(x_1|y_i)$$

We now have:

$$\mathbb{P}(y_i, \mathbf{x}) = \mathbb{P}(y_i) \prod_{j=1}^n \mathbb{P}(x_j|y_i)$$

and :

$$\mathbb{P}(y_i|\mathbf{x}) \propto \mathbb{P}(y_i) \prod_{j=1}^n \mathbb{P}(x_j|y_i)$$

We then select the most probable class

$$\hat{y} = \underset{x_i=1, \dots, k}{\operatorname{argmax}} (\mathbb{P}(y_i) \prod_{j=1}^n \mathbb{P}(x_j|y_i))$$

Further
algorithms

Can you guess why this algorithm can be called naive ?

We have two terms to estimate:

- $\mathbb{P}(y_i)$: either assume class equiprobability or estimate using the frequency in training dataset
- $\mathbb{P}(x_j|y_i)$: we need to decide on a conditional law

Possible assumptions include:

- If X_j is a **continuous variable** ($\mathbf{x}_j \in \mathbb{R}$), the continuous values associated within class i are distributed according to a Gaussian distribution parametrized with mean μ_i and variance σ_i

$$f(v \mid y_i) = \frac{1}{\sqrt{2\pi\sigma_i^2}} e^{-\frac{(v-\mu_i)^2}{2\sigma_i^2}}$$

Mathematical framework

Possible assumptions include:

- If X_j is a **continuous variable** ($x_j \in \mathbb{R}$), the continuous values associated within class i are distributed according to a Gaussian distribution parametrized with mean μ_i and variance σ_i

$$f(v \mid y_i) = \frac{1}{\sqrt{2\pi\sigma_i^2}} e^{-\frac{(v-\mu_i)^2}{2\sigma_i^2}}$$

- If X_j is a **binary variable** ($x_j \in \{0, 1\}^n$), the proportion of binary values observed within class y_i can be treated as a multivariate Bernoulli (p_{ij} being the frequency of event for variable x_j within class i):

$$\mathbb{P}(x_j \mid y_i) = \prod_{j=1}^n p_{ij}^{x_j} (1 - p_{ij})^{(1-x_j)}$$

Training dataset:

Height	Weight	Tail	Label
45	30	0	Labradoodle
30	25	1	Labradoodle
40	35	1	Labradoodle
20	15	0	English cocker
22	18	1	English cocker
25	20	1	English cocker

Individual to classify

Height	Weight	Tail	Label
25	31	1	?

Example: solution

Estimate:

$$\begin{aligned} & \mathbb{P}(\text{labradoodle} \mid \text{height} = 25, \text{weight} = 31, \text{tail} = 1) \\ & \propto \mathbb{P}(\text{labradoodle}) \times \mathbb{P}(\text{height} = 25 \mid \text{labradoodle}) \\ & \quad \times \mathbb{P}(\text{weight} = 31 \mid \text{labradoodle}) \\ & \quad \times \mathbb{P}(\text{tail} = 1 \mid \text{labradoodle}) \end{aligned}$$

$$\mathbb{P}(\text{labradoodle}) = \frac{1}{2}$$

$$\mathbb{P}(\text{height} = 25 \mid \text{labradoodle}) = \frac{1}{\sqrt{2\pi \times 38.89}} e^{-\frac{(25-38.33)^2}{2 \times 38.89}} = 0.006$$

$$\mathbb{P}(\text{weight} = 31 \mid \text{labradoodle}) = \frac{1}{\sqrt{2\pi \times 16.67}} e^{-\frac{(31-30)^2}{2 \times 16.67}} = 0.09$$

$$\mathbb{P}(\text{tail} = 1 \mid \text{labradoodle}) = \frac{2}{3}$$

$$\mathbb{P}(\text{labradoodle} \mid \text{height} = 25, \text{weight} = 31, \text{tail} = 1) = 0.00017$$

Example: solution

Estimate:

$$\begin{aligned} & \mathbb{P}(\text{cocker} \mid \text{height} = 25, \text{weight} = 31, \text{tail} = 1) \\ & \propto \mathbb{P}(\text{cocker}) \times \mathbb{P}(\text{height} = 25 \mid \text{cocker}) \\ & \times \mathbb{P}(\text{weight} = 31 \mid \text{cocker}) \\ & \times \mathbb{P}(\text{tail} = 1 \mid \text{cocker}) \end{aligned}$$

$$\mathbb{P}(\text{cocker}) = \frac{1}{2}$$

$$\mathbb{P}(\text{height} = 25 \mid \text{cocker}) = \frac{1}{\sqrt{2\pi \times 4.22}} e^{-\frac{(25-22.33)^2}{2 \times 4.22}} = 0.08$$

$$\mathbb{P}(\text{weight} = 31 \mid \text{cocker}) = \frac{1}{\sqrt{2\pi \times 16.67}} e^{-\frac{(31-30)^2}{2 \times 16.67}} = 1.39e - 10$$

$$\mathbb{P}(\text{tail} = 1 \mid \text{cocker}) = \frac{2}{3}$$

$$\mathbb{P}(\text{cocker} \mid \text{height} = 25, \text{weight} = 31, \text{tail} = 1) = 0.00$$

Further
algorithms

One of the most famous probabilistic classifier is **logistic regression**: probability distribution is expressed as the logit of the linear combination of features.

Using softmax function as activation layer in **neural networks** transforms output into a probability distribution consisting of K probabilities proportional to the exponentials of the input numbers.
